(54) Integrated wireless telecommunication and local area network system

(57) The invention includes a network system and method and apparatus for integrating wireless LAN and mobile telecommunications system. A network proxy and a terminal proxy are provided to allow a terminal (10) to connect to a network (1) and use any one of a number of connection interfaces. The proxies allow for switching between interfaces, and hide the switching from the higher layers of the communications protocol. Switching is managed in the link layer.

Description

[0001] This invention relates to a method and apparatus for integrating wireless LAN and mobile telecommunications and, in particular for an integrated Wireless LAN and telecommunication data card. The invention also relates to a network system, including at least one terminal and means for connecting to said network system.

[0002] The user of a portable computer or small mobile data terminal may be connected to a Local Area Network (LAN) by a number of different systems. The LAN may provide for wireless connection, using a Wireless LAN cord and an aerial. Alternatively, access via a telephone dial-up service, using for example a telecommunication data card and a mobile telephone, or an integrated card, may be provided to the user when outside the range of the wireless LAN. These systems provide the user with a degree of flexibility, but require the user to log-on to the LAN each time the mode of access (or interface) is altered.

[0003] There is a need for network access systems which are flexible, and yet require the minimum of hardware, since this increases the weight and the cost.

[0004] According to a first aspect of the invention there is provided a network system including: a terminal; and means for connecting the terminal to the network via at least two interfaces characterised in that means for switching the network connection between one interface and another are provided and further characterised in that a network proxy and a terminal proxy, adapted to redirect data packets in the link layer, are provided to support seamless switching between one interface and the other.

[0005] The invention thus provides simple, efficient and light weight method and apparatus for connecting to a network. The invention enables the user to stay connected to the network whilst roaming inside a building and whilst away from the building. The invention switches seamless between the two connections and enables a single card to be utilised to perform both functions. Using a single card has additional benefits in terms of power requirements and battery life.

[0006] The invention provides a mechanism that switches between communication interfaces without affecting the higher layer communications protocols, either in the mobile terminal or in the network. To the upper protocol layers, the invention provides a single network interface, regardless of the particular mode of connection.

[0007] The network proxy and the terminal proxy are functional blocks within the network architecture which support for seamless switching. The proxies may be tailored to each particular network and terminal combination.

[0008] Embodiments of the invention are described below, and with reference to the following figures, in which:

Figure 1 shows in outline a network configuration.

[0009] The information related to the capabilities of the network, are stored in a network proxy. The information relating to the capabilities of a terminal, 10, is stored in a terminal proxy. The terminal may connect to the network using conventional wireless LAN connection, using the combined data and Wireless LAN card 11, antennae 12 and 14 and the wireless LAN access point 16. Once connected, the terminal may communicate with other devices on the network via an ethernet backbone 1. Alternatively, the terminal may connect to the network using a telephone dial up service, via the data card 11 and cellular mobile telephone. The dialup service allows the terminal to log-on to the network, using the cellular mobile and public switched telephone services, 15, 17 and 18 via a dial up server 19.

[0010] To the upper protocol layers of the terminal, the combined card 11 appears as a single LAN interface, regardless of whether the terminal is currently connected via the wireless LAN or cellular data network. This means that none of the higher layer protocols need to modify their behaviour, or be aware of the mobile terminals movement. In the following examples, an ethernet network system running TCP/IP is used as an example.

[0011] The switching mechanism is responsible for hiding the movement of the mobile terminal from the higher protocol layers. When the mobile terminal is communicating via the wireless LAN interface, the application transmits packets (including address resolution requests) as normal.

[0012] The switching mechanism communicates with the wireless LAN interface and cellular data interface to determine the current signal strength of the two interfaces. The decision to switch can be made based upon a number of factors. One possibility is that when the wireless LAN signal strength drops below a given threshold the switching function activates the cellular data interface and then de-activates the wireless LAN interface. Switching decisions can also be made on the basis of: measured error rates; bandwidth; or cost.

[0013] When the switching mechanism decides to perform a switch two scenarios are possible: (1) switching from the wireless LAN interface to the cellular data interface or (2) switching from the cellular data interface to the wireless LAN interface. The functions performed by the switching function in both cases are described below:

1) Moving from the wireless LAN to the cellular data network

[0014] Initially the switching function activates the cellular data interface, registers with the cellular data network, and creates a dial-up connection to the configured address of the dial-up server. During the dial-up process the dial-up server will inform the mobile terminal of

the IP address it should use for this interface. The switching function must then send a mobile IP message to the network phone indicating the mobile terminals currently active IP address. The network proxy will then send a gratuitous ARP message over its IP subnetwork saying that traffic destined for the mobile terminal's home address should be sent to the home agent. The network proxy will thus receive data destined for the mobile terminal, this is then encapsulated in an IP header containing the dial-up interface IP address and transmitted to the mobile terminal via the dial-up server. When the integrated card receives the IP packet it must strip off the outer header and pass the packet up to the upper protocol layers. This means the upper protocol layers will always send and receive traffic with the wireless LAN IP address. When the wireless LAN interface is activated again, the card must transmit a gratuitous ARP to the network containing the wireless LAN IP and MAC addresses.

[0015] At this point, the wireless LAN interface on the card should be deactivated. Traffic arriving from the upper layers of the mobile terminal protocol stack will now be forwarded via the cellular data interface. The higher layer protocols will still assume that the mobile terminal is attached to a LAN, and hence will generate ARP requests for terminals residing on the same subnet as the wireless LAN. Via the dial-up connection from the cellular data interface, MAC addresses are not required since this is a point-to-point connection to the dial-up server. However the higher protocol layers expect a response. The following alternative approaches can be followed to provide the higher layers with a response so that they will continue to forward data traffic to the card for transmission.

- * The switching function captures the ARP request and generates an ARP response with a dummy MAC address which it forward to the higher layer protocols. This will enable the upper protocol layers to forward the queued traffic in a timely manner. The ARP request can then be discarded.
- * An alternative is to still forward the fake ARP response to the higher layers but to queue the ARP request so that when the switching function activates the wireless LAN interface again, all of the queued ARP requests can be transmitted. The responses would then be forwarded to the upper layer protocols to overwrite the ARP cache containing the fake MAC address.
- * An alternative is to send the fake ARP response to the higher layer protocols, but to also forward the ARP requests to the dial-up server. The dial-up server should then forward it over the local subnet to obtain a response. When the dial-up server receives a response it should forward it to the mobile terminal. In this case the integrated card should forward the ARP response to the higher protocol layers to update the ARP translation informa-

tion. This approach has the advantage that when the mobile terminal moves back to the wireless LAN it will already contain the correct ARP information.

[0016] Traffic from the mobile terminal will travel to the rest of the network via the cellular data interface. Traffic destined for the mobile terminal will be received by the dial-up server and forwarded to the mobile terminal.

2) Moving from the cellular data network to the wireless LAN

[0017] When the switching function makes the decision to move to the wireless LAN interface, this interface should be re-activated. When the wireless LAN interface is active the mobile terminal must send a gratuitous ARP message indicating its current IP address and MAC address. It must also send a message to the home agent indicating that it is now connected via the wireless LAN interface and what its current IP and MAC address is. The network proxy should then broadcast a gratuitous ARP stating the current mobile terminal's IP address and MAC address. The switching function should then trigger the necessary local ARP recovery function chosen from the alternatives above. At this point the cellular data interface should be de-activated. Traffic from the mobile terminal will then flow via the wireless access point to the rest of the subnet. Traffic arriving from other hosts will be forwarded to the mobile terminal by the wireless LAN access point.

[0018] The wireless LAN access point and dial-up server may be integrated into a single device which also implements the network proxy. In this case, all traffic to and from other hosts will always be routed via the same device, regardless of whether the integrated card wireless LAN or cellular data interface is active. This means that when the active interface changes gratuitous ARPs no longer need to be transmitted over the network. In this case when the switching function decides to change the active interface it sends a message to the integrated wireless forwarding device indicating the new active interface. This integrated forwarding device is then responsible for forwarding the traffic via this new interface. This has the benefit that the rest of the network is unaware of which interface on the integrated card is currently active. It also means that traffic follows an optimal route to the mobile terminal rather than having to be forwarded through multiple network devices. It also reduces the complexity of the switching function since mobile IP does not need to be implemented within the card.

[0019] The following proxies use the highest preferred network that has an acceptable signal strength. If a more preferred network becomes available again, the proxy swaps back to it. If the network currently in use becomes unacceptable and there are no higher preferred networks available the proxy drops to the next lower preferred network if that is available.

Terminal proxy**[0020]**

when connected to the wireless LAN
 while the wireless lan signal strength is greater than
 an acceptable level
 continuously gather the wireless lan signal strength
 and apply a smoothing function to remove transient
 signal strength fluctuations
 continuously gather the dial-up network signal
 strength and apply a smoothing function to remove
 transient signal strength fluctuations
 forward any data received from the terminal's
 higher layers over the wireless lan interface
 forward data received from the wireless lan inter-
 face to the higher layers of the terminal
 when the wireless lan signal strength is below an
 acceptable level
 send a handover signal to the network proxy indi-
 cating that the terminal is moving from a wireless
 lan to a dial-up connection
 create a dial-up connection to the network proxy
 when the dial-up connection is created deactivate
 the wireless lan interface when connected to the
 dial-up interface
 while the wireless lan signal strength is below an
 acceptable level and the dial-up signal strength is
 above an acceptable network (NB if these are the
 only two available networks a signal strength above
 zero may be acceptable)
 continuously gather the wireless lan signal strength
 and applying a smoothing function to remove tran-
 sient signal strength fluctuations
 continuously gather the dial-up network signal
 strength and apply a smoothing function to remove
 transient signal strength fluctuations
 forward any data received from the terminal's
 higher layers over the dial-up interface including
 address resolution requests
 forward data received from the dial-up interface to
 the higher layers of the terminal including address
 resolution responses
 when the wireless lan signal strength is above an
 acceptable level
 send a handover signal to the network proxy indi-
 cating that the terminal is moving from a dial-up
 connection to a wireless LAN connection
 activate the wireless LAN interface
 tear-down the dial-up connection to the network
 proxy
 when both the wireless LAN and dial-up signal
 strengths are below an acceptable level
 inform the higher layers that no networks are cur-
 rently available
 inform the network proxy no networks are currently
 available
 tear down the dial-up connection

**Network proxy (for wireless LAN bridge, dial-up server
and mobility support)****[0021]**

if the proxy receives data for terminal x
 if terminal x is accessible via the wireless LAN
 forward data over the wireless LAN interface to
 the terminal
 otherwise if terminal x is accessible via the dial-
 up interface
 forward data over the dial-up interface to the
 terminal
 otherwise if the terminal is not accessible by
 any network
 inform the sender of the packet that the termi-
 nal is not accessible
 if the proxy receives data from terminal x
 forward the data to the destination
 if the proxy receives a handover request from
 terminal x
 if the terminal is moving to a dial-up connection
 add the terminal to the list of current dial-up ter-
 minals
 when the dial-up connection is active and the
 terminal was previously connected to a wire-
 less LAN interface
 remove the terminal from the list of current
 wireless LAN terminals
 if the terminal is moving to a wireless LAN con-
 nection
 add the terminal to the list of current wireless
 LAN terminals remove the terminal from the list
 of current dial-up terminals

Claims

1. A network system including: a terminal; and means for connecting the terminal to the network via at least two interfaces characterised in that means for switching the network connection between one interface and another are provided and further characterised in that a network proxy and a terminal proxy, adapted to redirect data packets in the link layer, are provided to support seamless switching between one interface and the other.
2. A network system as claimed in claim 1 characterised in that the terminal has one link layer address which is used by the terminal regardless of the connecting interface.
3. A network system as claimed in claim 1 characterised in that the network proxy hides the switching from other devices connected to the network.
4. A network system as claimed in claim 1 character-

ised in that the terminal proxy hides the switching
from higher layers in the terminal.
